## ONS Longitudinal Study

## Quality of tracing at the 1991 Census

Tracing of LS records from the 1991 Longitudinal Study (LS) sample was more successful than at either of the previous censuses, with 98.3 per cent of LS members traced. However, a number of factors have been identified that were related to members of the 1991 LS sample not being traced. These include:

- being a young adult
- being divorced
- being born outside of the UK
- being in the economic position 'other inactive' or a full-time student
- living in London
- being a member of an ethnic minority
- living in certain types of communal establishment, such as defence establishments or psychiatric hospitals
- serving in the armed forces.

## Tracing rates at 1991 Census by sex and age

Females were more likely to be traced than males among the 1991 LS sample, with respective not-traced rates of 1.55 per cent and 1.71 per cent. For both sexes, tracing rates were lower among 20- to 39-year-olds and lowest among 20- to 24-year-olds (3.14 per cent of males and 2.50 per cent of females not traced).

For males, tracing rates were higher among those aged 55 and over, and highest among 70- to 74 -year-olds ( 0.94 per cent not traced). For females, tracing was higher among 5 - to 14 -year-olds and those aged 60 to 74 , with the highest tracing rates among 65 - to 69 -year-olds (1.12 per cent not traced).

Among people aged 20 and over, the likelihood of tracing tended to increase with age, which meant that older groups were more likely to be traced than younger ones. This pattern applied to both males and females under 75 . An exception was found among 50 - to 54 -year-olds who were less likely to be traced than people in adjacent age groups.

In general, below the age of 50 , females were more likely to be traced than males, whereas among the sample aged 50 and over, males were more likely to be traced. Exceptions were found among 0 - to 4 -year-olds, where males were more likely to be traced than females ( 1.22 per cent of males and 1.31 per cent of females not traced), and among 65- to 69-year-olds, where females were more likely to be traced than males ( 1.16 per cent of males not traced compared with 1.12 per cent of females).

| Age | Males |  |  |  | Females |  |  |  | Total |  |  |  |

## Notes:

${ }^{1}$ Source: Office for National Statistics Longitudinal Study (LS)
${ }^{2}$ LS members, usually resident in England and Wales
${ }^{3}$ 'Traced' means the LS members' records were found on the National Health Service Central Register before or at the 1991 Census-LS Link

## Tracing rates at 1991 Census by sex, age and marital status

Divorced LS members were the least likely of all marital-status groups to be traced in 1991 ( 2.32 per cent of males and 1.72 per cent of females not traced). Tracing was most successful among married people ( 1.35 per cent of males and 1.47 per cent of female not traced). Overall, females were more likely to be traced than males but males were more likely to be traced among the married and widowed groups.

Among never-married people, 0 - to 15-year-olds were most likely to be traced (1.29 per cent of males and 1.22 per cent of females not traced). Lower tracing rates were found among 20- to 39-year-olds, with the lowest tracing rates found for 30- to 34-year-old males ( 3.58 per cent not traced) and 25 - to 29 -year-old females ( 2.77 per cent not traced).

Among married people, tracing rates were higher at older ages and highest at 60 to 64 years ( 0.69 per cent of males and 0.90 per cent of females not traced). Widowed people aged 60 and over were also more likely to be traced but there was no consistent pattern of tracing by age among divorced people.

## Notes:

[^0]${ }^{2}$ LS members, usually resident in England and Wales
${ }^{3}$ 'Traced' means the LS members' records were found on the National Health Service Central Register before or at the 1991 Census-LS Link

## Tracing rates at 1991 Census by sex, age and economic position

There was an association between the economic position of Longitudinal Study (LS) members and their likelihood of being traced in 1991. This was also influenced by their age and sex. Retired people of both sexes were most likely to be traced ( 1.00 per cent of males and 1.25 per cent of females not traced). Tracing rates were also high for people in employment ( 1.65 per cent of males and 1.29 per cent of females not traced).

Among economically active LS members, those in employment were more likely to be traced (1.49 per cent not traced) than those out of employment ( 3.52 per cent not traced). Females in employment ( 1.29 per cent not traced) were more likely to be traced than males ( 1.65 per cent not traced), while males out of employment ( 3.35 per cent not traced) were more likely to be traced than females ( 3.91 per cent not traced).

Tracing was least likely for people in the 'other inactive' group (14.79 per cent of males and 9.86 per cent of females not traced). Students of both sexes ( 4.18 per cent of males and 3.16 per cent of females not traced) and males looking after the home or family ( 4.07 per cent not traced) were also less likely to be traced.

Focusing on the age groups shown in Table T91.3, for both sexes and with all positions of economic activity combined, tracing was most likely for those over the age of retirement (1.24 per cent not traced) and least likely among 25- to 34-year-olds (2.53 per cent not traced).

This pattern of tracing by age applied to most economic positions. However, for people in employment, tracing was most likely for people aged 45 to retirement age ( 1.06 per cent of males and 0.95 per cent of females not traced), while permanently sick females were least likely to be traced at retirement age and above ( 3.28 per cent of females not traced).

## Tracing rates at 1991 Census by sex and socio-economic group

In 1991, Longitudinal Study (LS) members in the armed forces were the least likely socio-economic group to be traced among both sexes ( 16.43 per cent of males and 25.65 per cent of females not traced). Tracing rates were also low for male personalservice workers ( 5.76 per cent not traced) although they were higher for females in the same group (1.66 per cent not traced).

For males, tracing was most likely for farmers and agricultural workers ( 0.78 per cent not traced), foremen and supervisors ( 0.80 per cent not traced) and skilled manual workers ( 0.99 per cent not traced).

Female foremen and supervisors ( 0.56 per cent not traced) were the most likely females to be traced. Tracing rates among females were also high for skilled manual workers ( 0.92 per cent not traced), junior non-manual workers ( 0.97 per cent not traced), and farmers and agricultural workers ( 1.03 per cent not traced).

Although males were typically less likely to be traced than females, in professional and managerial socio-economic groups males were more likely to be traced. Tracing failure among female professional workers with employees was 3.39 per cent compared with 1.81 per cent for males. Of self-employed professionals, 2.01 per cent of females were not traced, while males in the same group were more likely to be traced ( 1.16 per cent not traced).

## Economically active

Very similar patterns of tracing rates by socio-economic group were found among LS members who were economically active (Table T91.4b) as were found among active and inactive LS members combined.

In 1991, armed forces personnel were least likely to be traced among both sexes (16.93 per cent of males and 29.08 per cent of females not traced). Tracing rates were also low for male personal-service workers ( 6.36 per cent not traced) but higher for females in the same group ( 1.78 per cent not traced).

For economically active males, tracing was most likely for farmers and agricultural workers ( 0.82 per cent not traced), foremen and supervisors ( 0.86 per cent not traced), and skilled manual workers ( 1.00 per cent not traced).

Female foremen and supervisors ( 0.64 per cent not traced) were the most likely females to be traced. Tracing rates among females were also high for skilled manual workers ( 0.93 per cent not traced), junior non-manual workers ( 0.98 per cent not traced) and farmers and agricultural workers ( 0.99 per cent not traced).

Although economically active males were typically less likely to be traced than females, in professional and managerial socio-economic groups males were more likely to be traced. Tracing failure among female professional workers with employees was 3.00 per cent compared with 1.83 per cent for males. While 2.15 per cent of self-employed
professional females were not traced, males in this groups were more likely to be traced (1.20 per cent not traced).

## Tracing rates at 1991 Census by sex and social class

## All LS members (aged 16 and over economically active and inactive)

In 1991, tracing rates were higher for Longitudinal Study (LS) members in non-manual social classes (1.27 per not traced) than for those in manual classes (1.32 per cent not traced).

Tracing rates were highest in the skilled manual and skilled non-manual classes. For males, tracing was most likely for the skilled manual class (1.17 per cent not traced), followed by the skilled non-manual ( 1.26 per cent not traced). For females, tracing was most likely for the skilled non-manual class ( 0.97 per cent not traced) followed by the skilled manual ( 1.22 per cent not traced).

There were differences between the sexes in tracing rates for the various social classes. Although males were typically less likely to be traced than females, within the professional class males were more likely to be traced (1.79 per cent of males not traced, compared with 3.30 per cent of females). Tracing was also more likely for males in the skilled manual class (1.17 per cent not traced) than for females (1.22 per cent not traced).

Tracing failure was highest among people in the armed forces ( 16.43 per cent of males and 25.65 per cent of females not traced). [Do armed forces personnel count as a social class?]

## Economically active

Very similar patterns of tracing rates were found among the social classes of LS members who were economically active as were found among the social classes of economically active and inactive LS members combined.

Table T91.5b shows that in general, tracing was more likely for people in non-manual social classes (1.31 per not traced) than for those in manual classes ( 1.40 per cent not traced) in 1991.

Tracing rates were highest for economically active people in skilled manual and skilled non-manual social classes. For males, tracing was most likely for the skilled manual class (1.20 per cent not traced), followed by the skilled non-manual (1.27 per cent not traced). For females, tracing was most likely for the skilled non-manual class ( 0.99 per cent not traced) followed by the skilled manual class (1.26 per cent not traced).

There were some differences between the sexes in tracing rates for the various social classes. Although economically active males were typically less likely to be traced than females, within the professional class males were more likely to be traced ( 1.81 per cent of males not traced, compared with 3.00 per cent of females). Tracing was also more likely for males in the skilled manual class ( 1.20 per cent not traced) than for females (1.26 per cent not traced).

Tracing failure was highest among people in the armed forces (16.93 per cent of males and 29.08 per cent of females not traced).

## Tracing rates at 1991 Census by sex, age and country of birth

In 1991, tracing was most successful among Longitudinal Study (LS) members born in England and Wales ( 0.81 per cent of males and 0.79 per cent of females not traced). Tracing failure for people born outside England and Wales averaged at around 10 per cent.

In particular, tracing rates were lowest for people born in the USA (44 per cent of males and a third of females not traced). Low tracing rates were also found among people born in West Africa (20.58 per cent of males and 16.14 per cent of females not traced) and the countries of the 'Old Commonwealth' (15.12 per cent of males and 9.27 per cent of females not traced), as well as among those in the 'elsewhere and not stated' category (around 17 per cent not traced). Among people born outside the UK, tracing rates were relatively high for those born in East Africa ( 5.07 per cent not traced), the Irish Republic (6.61 per cent not traced), the 'Caribbean Commonwealth' countries (6.64 per cent not traced) and India ( 6.68 per cent not traced).

Males were typically less likely to be traced than females. However, among people born in India, Pakistan and Bangladesh, the 'East African Commonwealth', and the 'Mediterranean Commonwealth', males were more likely to be traced.

Focusing on the groups in Table T91.6b, tracing rates for all countries of birth taken together were lowest among 25 - to 34 -year-olds ( 2.53 per cent not traced). Among males, tracing was highest for those aged 60 and over ( 1.10 per cent not traced) while, for females, the highest tracing rates were found among 0 - to 14 -year-olds ( 1.21 per cent not traced).

However, among people born in the countries of the 'New Commonwealth', tracing was least likely for people under 25 (around 10 per cent not traced) and most likely for 35 - to 44 -year-olds. This distinctive pattern of tracing rates by age was most pronounced for people born in the 'African Commonwealth' among whom 17.51 per cent of 0 - to 14-year-olds were not traced.

## Tracing rates at 1991 Census by sex, age and ethnic group

A question on ethnic group was included in the 1991 Census for the first time and 7 per cent of Longitudinal Study (LS) members described themselves as a member of an ethnic minority.

Overall, tracing rates were lower for members of ethnic minority groups than for White LS members ( 1.25 per cent of males and 1.09 per cent of females were not traced).

Among ethnic minorities, Black Africans were least likely to be traced ( 23.42 per cent of males and 19.12 per cent of females were not traced).

Tracing rates were also low for Chinese LS members ( 9.89 per cent of males and 11.88 per cent of females not traced) and 'Other Asian' people ( 13.46 per cent not traced). Among all males from an ethnic minority group, tracing was most likely among Indians (4.88 per cent not traced). For females, Black Caribbeans were most likely to be traced (4.68 per cent not traced).

Although females were more likely to be traced than males overall, among Asian ethnic groups (and 'Other groups - other') males were more likely to be traced than females. Similarly, tracing rates by country of birth were also higher for males born in India, Pakistan and Bangladesh than for females.

Focusing on the age groups shown in Table T91.7, tracing rates for all ethnic groups taken together were lowest for both males and females aged 25 to 34 ( 2.84 per cent of males and 2.23 per cent of females not traced). Tracing rates were highest for males over 60 ( 1.10 per cent not traced) and females aged 0 to 14 years ( 1.21 per cent not traced). However, there was a distinctive difference from this pattern for Indian people whose lowest not-traced rate was for those over 60 ( 8.55 per cent of males and 12.31 per cent of females not traced). Chinese males were also least likely to be traced at ages 60 and over (13.7 per cent not traced) while for Chinese females, 45- to 59-yearolds were least likely to be traced (19.15 per cent not traced).

Among White people, tracing tended to increase with age for those aged 25 to 60. However, patterns of age variation within most ethnic groups were less clear. In part, this is because not-traced rates for some groups are based on small numbers of LS members.

| Ethnic group and age | Males |  |  |  | Females |  |  |  | Total |  |  |  |

${ }^{3}$ 'Traced' means the LS members' records were found on the National Health Service Central Register before or at the 1991 Census-LS Link

## Tracing rates at 1991 Census by sex and region of usual residence

People living in Greater London in 1991 were less likely to be traced ( 5.28 per cent of males and 4.68 per cent of females not traced) than people living elsewhere. Tracing was also low in East Anglia, with 2.27 per cent of people not traced.

People living in the North of England were most likely to be traced ( 0.78 per cent of males and 0.72 per cent of females not traced). People from Yorkshire and Humberside, the East Midlands and the North West were also likely to be traced, with not traced rates of less than one per cent.

Overall, tracing of females was higher than of males ( 1.55 per cent of females not traced compared with 1.71 per cent of males). Only in the North West were males more likely to be traced than females ( 0.91 per cent of males and 0.97 per cent of females not traced).

## Tracing rates at 1991 Census by sex and type of establishment

In 1991, tracing was more successful among people living in private households (1.55 per cent not traced) than among those living in communal establishments ( 4.56 per cent not traced).

Among the different types of communal establishment, there were differences between the sexes in the likelihood of tracing. For males, tracing was most likely for people in nursing homes (2.24 per cent not traced). Whereas, of all females, those in educational establishments had the highest tracing rates ( 2.52 per cent not traced).

The lowest tracing rates were found for residents of defence establishment (12.57 per cent of males and 11.76 per cent of females not traced), people in psychiatric hospitals ( 9.04 per cent of males and 8.44 per cent of females not traced) and those in hotels ( 6.89 per cent of males and 6.36 per cent of females not traced).

Females ( 1.55 per cent not traced) were more likely to be traced than males (1.71 per cent not traced) overall. However, among residents of nursing homes, males were more likely to be traced.

| Establishment type | Males |  |  |  | Females |  |  |  | Total |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
